

WHAT PATTERN ANALYSIS DO WE ACTUALLY HAVE FOR BILLING

Six patterns on the shelf. Which walk on Tuesday.

Six billing-adjacent patterns already on record. Not aspirational — each one is drawn from what has been said and what has been built. Tobias marks each row walkable / demo-only / not yet, and we know what goes in front of Sera on Tuesday.

#	PATTERN	WHAT IT DETECTS	DATA IT RUNS ON TODAY	WHERE IT LANDS	STATE
P1	Recurring-edit to master-data	Same operator, same account/line item, same correction month after month on the draft sales order. Signals a master-data source-of-truth problem, not a review-queue problem.	Sales-order + change tables, manually extracted into the Azure tenant when Datasphere wiring for that slice paused. Walkable demo runs off the extract today.	Prioritized list to Billing operations: contract, Bullhorn profile, billing rate, or role assignment to correct. Ranked by recurrence × annual monetary weight.	
P2	Suite-total vs. profitability trend	Whether the auto-bill suite total and the profitability line are trending up or down together. Divergence flags leakage the suite itself won't show — the suite closes the month, it doesn't question it.	Auto-bill suite output + downstream margin against Datasphere-reconstituted profitability. This is the trend pair that sits on top of Jaci's operational floor.	Chart in Power BI for Jaci; the divergence months become the intake list for P1 root-causing.	
P3	Time-recording undercount	Last-minute time submissions systematically undercount hours vs. the same operators' pattern earlier in the period. Bullhorn side already assembled in AWS by Epiq's own team.	Bullhorn time data on the AWS side. Delivered access layer plugs into what Epiq already assembled — not Datasphere, not Azure. First honest high-value pattern on the enlarged dataset.	Ranked list of operators + accounts before the invoice runs — not after. Lands in Teams or email; corrected time books before auto-bill.	
P4	Missing-line-item risk (forward)	Line items that should be present but are not — based on contract terms, role assignments, and prior-month baselines. Symmetric to present-line-item risk; most leakage lives on the missing side.	Contract master + prior-month invoice lines + role assignments. Runs against the same Azure extract used by P1; delivered access layer reads it.	Forward-looking risk register: what should invoice next month by contract, by account, with the operator responsible for booking it.	
P5	Contract-mix / synergy	How the mix of contract types and cross-service work is trending against plan — not a billing-error question, an FP&A question. Different recipient, same underlying model.	Reconstituted SAP profitability in Datasphere (Nick's lane) + contract master. Historical reconstitution is already delivered against the incomplete-S/4-activation pattern.	Nick Burns and John Mullen — mix and synergy views in the delivered Teams access layer. Not on the Sera-Jaci demo path; noted so Tobias can call it in or out.	
P6	S/4 margin-analysis retrofit	Margin-analysis views rebuilt in Datasphere against the underlying documents where the prior SI activated S/4 without turning on margin analysis in the Universal Journal. Not a Jaci pattern — the reference architecture Epiq already runs.	Datasphere against S/4 source documents; OSS tickets on file. Delivered.	Reference architecture. Same pattern travels to any S/4 customer with an incomplete activation (margin analysis, group reporting, embedded planning). This is the SAP-carries-the-story point.	

State column, in Tobias' hand: L = live and clickable · D = demo-only walkthrough · N = not yet · X = do not show
